Как биткойн-холодные кошельки потеряли 70 миллионов долларов в результате атаки, которая так и не затронула устройства

Galaxy Research заявила, что слабая генерация начальных данных позволяет злоумышленнику воссоздать вероятные закрытые ключи в автономном режиме, забрать более 1000 BTC с почти 1200 кошельков и продолжить поиск, даже не получая доступа к устройствам.

предположить, что транзакции транслировались пакетами, а не непрерывно.

Вырученные средства находятся на четырех адресах и никуда не перемещались. В первых сообщениях фигурировал только один из этих адресов, поэтому сумма выросла.

Размер атаки намного меньше, чем у некоторых более масштабных атак этого года, но именно механизм делает ее необычной и объясняет, почему она имеет такое большое значение.

Почему взлом кошелька Coldcard — это более серьезная проблема, чем большинство других взломов

В большинстве случаев при краже криптовалюты злоумышленники получают доступ к чему-то. Взламывают биржу, обманывают смарт-контракт, похищают ключ с ноутбука. Защита всегда заключалась в дистанцировании, и именно это обеспечивает аппаратный кошелек. Храните ключ на устройстве, которое никогда не подключается к интернету, и теоретически злоумышленнику нечего будет трогать.

- 1 Flaw shrinks the possible keys to about four billion
- 2 Attacker generates candidates on their own machine
- 3 Checks each one against the public blockchain
- 4 Match found, funds swept

✗ **Air-gapping is irrelevant**

Every step runs on the attacker's hardware. The victim's device can be powered off in a vault on another continent.

Because the search runs entirely on the attacker's side, it can be paused and resumed at will. Galaxy Research warned further waves are likely if owners do not move their funds, and there is no test an owner can run to find out whether their wallet is in the range.

Для большинства случаев кражи криптовалют требуется доступ к ключу. В этом случае ключ был восстановлен. (Шаурья Малва/CoinDesk)

При создании кошелька устройство должно сгенерировать настолько большое и непредсказуемое число, что угадать его невозможно.

Это число является начальным значением, и каждый адрес и закрытый ключ генерируются на его основе по фиксированным общедоступным правилам. Прошивка Coldcard должна была получать это число от специального аппаратного генератора случайных чисел. Однако внутренняя настройка сборки предписывала не использовать этот генератор, а проверка в вспомогательной библиотеке проверяла только наличие настройки, а не ее активацию.

Four billion is a large number to a person but a small one to a computer. An attacker generates candidate seeds on their own hardware, derives the addresses each would produce, and checks those addresses against the public blockchain, which anyone can download.

Every step of that runs on the attacker's machine. The victim's device is not involved at any point and could be powered off in a safe on another continent.

Galaxy's breakdown shows the process running. Of the drained wallets, 1,183 used the modern native segwit address format, seven used an older standard and six an older one still. Nobody targets a specific victim across three address formats at once.

That is systematic enumeration, checking each candidate seed against every path it might have produced. The operator can widen the search, refine it and return whenever they choose.

Galaxy warned further waves are likely if owners do not move their funds.

fingerprint of software working through candidate seeds and testing every path each one could have produced, which is a process that can be paused and resumed at will.

The victims span three address formats, which is what a scanner looks like. (Shaurya Malwa/CoinDesk)

Nor can an owner determine whether they are exposed. There is no test to run against your own wallet that reveals whether your seed sits inside the reproducible range.

Attack might not be fully finished

Coinkite, Coldcard's maker, has warned Mk3 owners and says its newer devices are unaffected, while Block's report places the Mk2, Mk4, Q and Mk5 in scope as well. Until that is resolved, anyone who generated a seed on the affected firmware has to assume the worst rather than verify it.

The attacker did make one mistake, however.

Block's Clay Garrett said on X that the operator used a paid account at a “well-known blockchain data provider” to query the source addresses during the sweeps, and that the provider's internal logs matched the suspected workflow with what he called extraordinary specificity, down to the number, timing and sequence of requests.

1/ During our investigation of the Coldcard drain yesterday, we identified an unusual pattern in the sweeps. That pattern led us to a hypothesis that has since been

Cold storage promises that a key is unguessable. Everyone read it as a promise that a key is unreachable, and the cost of finding and exploiting flaws in the first kind keeps falling.

Anthropic published research on Tuesday showing one of its models halving the security of a candidate post-quantum algorithm in 60 hours, against a design that had survived two years of expert review.

Storing a key safely is now the easier half of the problem.
