Искусственный интеллект на практике

OpenAI анонсирует свою "следующую крупную модель" Astra, представив десять ранее нерешенных математических задач

Matthias Bastian  1 августа 2026 г.

Ключевые моменты

- OpenAI работает над новым семейством моделей искусственного интеллекта под названием "Astra," предназначенных для решения долгосрочных задач и сложных проблем путем координации совместной работы нескольких агентов.
- Генеральный директор компании Сэм Альтман уже продемонстрировал Astra в Вашингтоне. В настоящее время модели проходят тестирование и станут первыми, которые пройдут запланированную проверку со стороны правительства США, требующую официального одобрения перед публичным выпуском.

- Этот проект отражает стремление OpenAI создавать системы искусственного интеллекта, способные непрерывно работать над решением задач в течение нескольких часов или даже дней.

Задать вопрос по этой статье...

Темы

- Решения Astra обойдутся примерно в 2000 долларов по тарифам API
- Сообщается, что OpenAI разрабатывает Astra — семейство моделей, предназначенных для решения задач в течение нескольких часов или дней
- Astra станет первой моделью, протестированной в рамках новой нормативно-правовой базы США
- Долгосрочная цель — исследования в области автономного искусственного интеллекта

Обновление — 1 августа 2026 г.

- Добавлено объявление об Astra и математическая статья.

Обновление:

OpenAI опубликовала математический отчет, в котором впервые официально подтвердила название модели — Astra. Компания заявляет, что внутренняя версия Astra, ее "[следующее крупное семейство моделей](#)," решила десять открытых проблем в математике и теоретической информатике. Математики не продвинулись ни в одной из них как минимум за десять лет, а в большинстве случаев — гораздо дольше.

[Результаты](#) охватывают самые разные области — от многомерной геометрии и теории кодирования до теории групп, квантовой сложности, решёточной

криптографии и экстремальной комбинаторики. Одно из доказательств устанавливает существование несофических групп, решая один из важнейших открытых вопросов теории групп.

Томас Блум, математик из Манчестерского университета, владелец сайта erdosproblems.com, [назвал эти результаты «важной новостью» на X](#). Он считает их более значимыми, чем [опубликованный в мае контрпример к гипотезе о единичном расстоянии](#). «Может быть, это и не так важно, как доказательство гипотезы о единичном расстоянии, но с точки зрения построений это большой шаг», — написал Блум.

[Bloom also rejected the idea that AI is replacing mathematicians](#), arguing that the claim makes little sense when the AI draws on more than a century of mathematical

theory, was built by mathematicians, and was trained on everything mathematicians have ever written.

Noam Brown, one of the researchers behind the [test-time reasoning technology](#) used by Astra, [said on X](#) that OpenAI had also tried and failed to crack other major problems. "Sadly, no Millennium Prize Problems (yet)," he wrote. The Clay Mathematics Institute offers \$1 million for solving each of the seven Millennium Prize Problems, but only one has been solved since the prizes were announced in 2000. Brown added, "But also, we didn't spend a lot on each problem. It's possible to push test-time compute much further." He called Astra a "major step for scientific reasoning."

AD

Astra's solutions would cost about \$2,000 at API rates

OpenAI says the tokens used to generate all ten solutions would have cost about \$2,000 at Sol's API rates. After the model produced its arguments, humans worked with the same model to turn them into research papers. The model also formalized each proof in [Lean](#), creating machine-checkable certificates of mathematical correctness, and OpenAI published a [walkthrough of the model's reasoning process for each solution](#).

OpenAI said its researchers helped prepare the papers and formalize the proofs, and that the company takes responsibility for their accuracy. The mathematical arguments themselves, however, came from Astra.

The company argued that claiming human authorship for a proof generated entirely by AI would misrepresent both the system's contribution and the nature of genuine human intellectual work, pointing to the [Leiden Declaration on AI and Mathematics](#) as a reference for how credit should be assigned in AI-assisted research.

Original article:

OpenAI is reportedly building Astra, a model family designed to work on problems for hours or days

OpenAI is working on a new model family tentatively called "Astra" that's meant to be far more capable at long-running tasks than anything the company has shipped so far.

CEO Sam Altman demoed Astra to politicians and regulators in Washington, D.C., this week. OpenAI stressed the system's ability to coordinate multiple agents over extended periods to tackle especially hard problems. The company pointed to complex projects and advanced math as potential use cases. [The Information](#) reported the details, citing three people familiar with the plans.

According to the report, Astra would form a new model class alongside OpenAI's existing Sol, Terra, and Luna families. Whether it ships as GPT-6 or as a variant within the GPT-5 line, something like GPT 5.7, hasn't been decided yet. There's no release date either.

OpenAI also plans to publish a report soon showing how the company used its most advanced AI to [solve ten previously unsolved math problems](#). The goal is to show what its current models can already do.

Astra would be the first model tested under a new US regulatory framework

The models are already in testing, according to The Information. They're expected to be the first to go through the Trump administration's planned [new AI framework](#),

which would require AI models to be submitted to the federal government before public release. The administration aims to finalize the framework by the end of this week.

One key question is whether the models can avoid compounding errors during long-running workflows and correct themselves when a process drifts off course as the [context keeps growing](#). That remains a major [weakness in today's agentic systems](#). Multi-agent setups like Astra can also [perform worse](#) on tightly linked tasks such as planning because coordination overhead and compounding errors can wipe out any gains.

The long-term goal is autonomous AI research

The Astra rumors line up with earlier statements from the company. Chief Scientist Jakub Pachocki said on OpenAI's official podcast last summer that the company wants to build AI systems that can [work on a problem for hours or days](#). Current systems are often limited to short tasks, but OpenAI wants models that can plan, reason, and experiment over longer time horizons. Late last year, the company even raised the question of how to think about systems that could [solve tasks a human would need centuries to complete](#).

By March 2028, OpenAI wants to have a [fully autonomous AI researcher](#) that can run research projects on its own, and that system would also depend on long-running AI processes. As early as this September, the company plans to have an AI system with research-intern-level skills that would significantly speed up human scientists. Astra could end up being that system.

Pachocki also said these systems will need far more compute. OpenAI's long-term [infrastructure plans reflect that ambition](#). Whether the startup's revenue grows fast enough to [fund that massive buildout](#) remains an open question.
