Неооблачные технологии, суверенный ИИ и Postgres: новая операционная модель для регулируемых предприятий

По мере внедрения логического вывода на основе ИИ предприятия обращаются к неооблачным технологиям, Postgres и суверенному ИИ, чтобы сохранить контроль над данными и вычислениями.

В корпоративном искусственном интеллекте доминирует логический вывод, и с его появлением возникла неудобная реальность: данные почти всегда передаются на вычислительные ресурсы. Каждый вызов логического вывода перемещает конфиденциальную корпоративную информацию из систем, в

создает проблемы, которые усугубляются по мере роста масштабов. растут затраты, повышается уязвимость системы безопасности, а количество копий данных, которые не синхронизированы с операционной реальностью, увеличивается.

На самом деле предприятиям нужно другое: сохранять данные и интеллектуальную собственность в целости в базе данных, а не создавать множество копий и устранять возникающие несоответствия.

Исследование, в котором приняли участие более 2050 руководителей высшего звена из крупных компаний по всему миру, показало, что 95% организаций намерены в течение следующих 780 рабочих дней создать собственные платформы искусственного интеллекта и обработки данных. Однако только 13% успешно достигли этой цели. Организации, которым это удалось, получают почти в пять раз больше прибыли от инвестиций, чем те, кто все еще пытается внедрить ИИ.

Лидеров от последователей отличает не качество моделей. А стратегия развития инфраструктуры.

Наиболее успешные организации придерживаются подхода «суверенитет по замыслу». Более 75% из них работают в нескольких облачных и локальных средах, а не полагаются на одного гиперскейлера. Они создают ИИ с учетом собственных бизнес-требований, нормативных требований и особенностей эксплуатации, а не адаптируют эти требования под архитектуру облачного провайдера.

EDB Postgres® AI (EDB PG AI) — это первая открытая суверенная платформа данных и искусственного интеллекта корпоративного уровня, безопасная, соответствующая требованиям и масштабируемая, доступная как локально, так и в облаке. EDB PG AI, созданная на базе Postgres, ведущей в мире базы данных, объединяет транзакционные, аналитические рабочие нагрузки и задачи искусственного интеллекта, позволяя организациям использовать свои

19 December 2024

As AI moves from experimentation into production, CIOs are discovering that training models is relatively easy. Running them efficiently, securely and compliantly across thousands of operational workloads is where the real challenge begins.

The shift from training to inference

Training is a discrete event. Inference is an ongoing business process.

odel may be trained once, but it could be called millions of times each day. Every fraud assessment, insurance claim review, customer service interaction,

“What separates the leaders from the followers is not model quality. It is infrastructure strategy.”

This distinction fundamentally changes enterprise infrastructure requirements.

Training workloads prioritize compute density and GPU availability. Inference workloads prioritize latency, governance, reliability and cost control. They must operate where business data resides and where compliance requirements can be enforced.

For heavily regulated industries such as financial services, healthcare, telecommunications, energy and the public sector, inference cannot simply occur in whichever region offers the lowest compute cost. Data sovereignty requirements, audit obligations and security mandates often dictate exactly where workloads must execute.

The challenge therefore becomes much larger than AI itself. Organizations need an operating model capable of bringing together compute, data and governance without sacrificing flexibility.

Why neoclouds are emerging as a critical layer to cross the chasm to production

This is where neoclouds have become increasingly important.

Unlike traditional hyperscalers, **neoclouds are purpose-built** around AI infrastructure. Their focus is not delivering hundreds of generic cloud services but rather optimizing for GPU access, AI performance, and flexible consumption models.

For many enterprises, neoclouds offer a compelling answer to the growing demand for specialized AI compute. They provide access to the latest accelerator technologies while enabling organizations to scale workloads without the complexity often associated with large cloud environments.

closer to data rather than moving data closer to models.”

However, neoclouds solve only one part of the enterprise AI equation.

AI does not create value in isolation. Models require context. They need access to customer records, transaction histories, operational workflows, policy documents, supply chain information and enterprise knowledge. Moving these assets into separate AI environments creates duplication, latency and governance challenges.

The future of AI architecture therefore depends on bringing models closer to data rather than moving data closer to models.

Why Postgres has become the enterprise AI foundation

As organizations look for a common platform that supports both operational and AI workloads, **Postgres** has emerged as a natural foundation.

Postgres already serves as the operational backbone for many of the world's most important applications. It combines transactional reliability, extensibility, and scalability with the openness that enterprises increasingly demand. 70%+ of AI-related application development is happening on Postgres.

What makes Postgres particularly relevant in the AI era is **its ability to become more than a database**. It can serve as a governed memory layer for AI systems, integrating operational data, application context, permissions, observability, and retrieval capabilities into a single architecture.

This dramatically reduces complexity.

Instead of maintaining separate infrastructures for transactional systems, vector stores, AI memory layers, and governance frameworks, organizations can consolidate around a trusted operational platform that already supports their mission-critical workloads.

For CIOs seeking to balance innovation with control, this architectural simplification represents a significant strategic advantage.

For banks, sovereignty means maintaining control over financial data and regulatory obligations. For healthcare organizations, it means protecting patient information while enabling innovation. For governments, it means ensuring national and citizen data remains under appropriate jurisdictional control.

The rise of AI has amplified these concerns.

Organizations increasingly need assurance that models, data, policies and operational controls can remain within designated environments while still benefiting from advances in AI technology.

This requirement is driving demand for **sovereign AI** architectures capable of operating across clouds, private infrastructure and on-premises environments.

The challenge is creating consistency across these environments without introducing operational complexity.

EDB Postgres AI: connecting sovereign data and sovereign AI

EDB Postgres AI addresses this challenge by bringing together operational Postgres, AI capabilities and hybrid infrastructure management into a unified platform.

Rather than forcing enterprises to choose between innovation and control, EDB Postgres AI enables organizations to deploy AI where their data already resides. Through capabilities spanning operational databases, analytics, agentic AI workloads and hybrid management, organizations can create a consistent operating model across sovereign environments.

This approach is particularly relevant for regulated industries where moving sensitive information into external AI services may introduce compliance, security or governance concerns.

By enabling inference close to operational data, organizations reduce data movement, improve performance, and strengthen their compliance posture. At the same time, they maintain the flexibility required to leverage emerging AI technologies and modern infrastructure models.

reduce data movement, improve performance, and strengthen their compliance posture.”

The result is a platform that aligns with the realities of enterprise AI rather than the assumptions of consumer AI.

“The reality is that the new AI at scale world needs a new infrastructure. That isn’t just the compute; it’s the governance, heuristic data access and level of observational and orchestration control that are absolute, governed, agile and work for humans and agents.” Nancy Hensley, CPO, EDB

The new enterprise AI stack

The emerging enterprise AI architecture is increasingly built around complementary rather than competing technologies.

Infrastructure layer	Primary role	Strategic value
Neoclouds	Specialized AI compute and GPU infrastructure	Access to cutting-edge AI acceleration and flexible scaling
Public Hyperscalers	Broad cloud services and global reach	Ecosystem breadth and service diversity
Postgres	Operational data foundation	Trusted, governed and scalable enterprise data platform
EDB Postgres AI	Sovereign AI and hybrid management layer	Enables AI, analytics and operational workloads to run consistently across sovereign environments
Enterprise Governance	Security, compliance and policy controls	Ensures AI aligns with regulatory and business requirements

Together, these layers create an architecture capable of supporting the complete AI lifecycle—from experimentation and model training through production inference and continuous optimization.

The CIO imperative

while maintaining control over cost, governance, and risk.

Their answer is increasingly consistent.

They are adopting multi-cloud and hybrid strategies rather than relying on a single cloud. They are prioritizing sovereign architectures rather than centralized data movement. They are building around open operational foundations rather than proprietary lock-in. Most importantly, they are recognizing that AI success depends on bringing intelligence to data, not data to intelligence.

Neoclouds provide the compute layer required for modern AI. Postgres provides the operational foundation required for trusted enterprise systems. EDB Postgres AI connects these worlds through a sovereign architecture designed for the realities of regulated industries.

As AI transitions from experimentation to operational necessity, the winning enterprises will be those that can make inference secure, governed, low-latency, and economically sustainable at scale.

In the next era of enterprise AI, the greatest business value will not come from model selection or raw GPU access. It will come from infrastructure strategy built around data – keeping intelligence close to where data already lives, governed, trusted, and ready to act.
